Comprehensive Analysis of the Tax Implications of Automated Cryptocurrency Trading and DeFi Operations under Polish Jurisdiction

1. Introduction and Executive Overview

The rapid evolution of decentralized finance (DeFi), algorithmic high-frequency trading, and non-custodial smart contract infrastructure presents a profoundly complex regulatory and taxation landscape. As decentralized exchanges (DEXs) and autonomous lending protocols facilitate billions of dollars in daily volume, individual software developers deploying algorithmic bots face unprecedented classification challenges under traditional domestic tax regimes. The central thesis of this exhaustive research report examines the precise tax treatment of a Polish tax resident operating a sole proprietorship (*Jednoosobowa Działalność Gospodarcza* - JDG) under a 12% flat-rate tax (*ryczałt od przychodów ewidencjonowanych*) for software development, who simultaneously architects, deploys, and maintains automated trading bots.

These bots are designed to execute highly complex, capital-intensive operations across multiple blockchain networks (e.g., Ethereum, Arbitrum, Base, Polygon). Specifically, the operations include lending market liquidations—monitoring under-collateralized debt positions on protocols like Aave or Compound to extract liquidation penalties—and high-frequency DEX-to-DEX arbitrage, often utilizing atomic flash loans to extract Maximal Extractable Value (MEV) from transient price discrepancies.

The findings of this analysis indicate a paradoxical, yet structurally highly favorable, tax architecture under current Polish interpretations. Despite the high-frequency, algorithmically intensive, and continuously operating nature of the trading bots, the operational activity can be cleanly segregated from the software development JDG. Current jurisprudence and interpretative practice classify this activity strictly as private capital gains (taxed at a flat 19% via PIT-38), contingent upon the absolute avoidance of managing third-party capital. However, this optimal ontological classification introduces severe mechanical disadvantages regarding the deductibility of operational costs. The rigidity of the Polish tax code renders server hosting, smart contract deployment costs, flash loan premiums, and intra-crypto network gas fees entirely non-deductible, creating a significant "cost trap" for high-frequency operators. Furthermore, the multi-jurisdictional deployment of node infrastructure and virtual private servers (e.g., in Germany or Japan) is analyzed and determined not to constitute a Permanent Establishment (PE) under OECD guidelines, ensuring exclusive tax residency and liability remain anchored in Poland.

This report provides a meticulous deconstruction of statutory provisions, recent jurisprudence,

Individual Tax Rulings (*Interpretacje Indywidualne*) issued by the Director of the National Revenue Information (KIS), and the practical reporting methodologies required to maintain stringent compliance within this hybrid technological and legal structure.

2. Ontological Classification: Business Income versus Capital Gains

The foundational question that dictates the entire subsequent tax treatment framework is one of classification: Does the continuous deployment of an automated bot executing potentially thousands of transactions per day constitute an unregistered business activity, or does it remain securely within the realm of private capital gains? The distinction carries massive financial implications, dictating the applicable tax forms, the tax rates, the deductibility of expenses, and the imposition of social security (ZUS) obligations.

2.1 The Definition of Business Activity in Polish Tax Law

To begin the analysis, one must evaluate the statutory definition of business activity. Under Article 5a point 6 of the Polish Personal Income Tax (PIT) Act, business activity (*pozarolnicza działalność gospodarcza*) is defined as an activity of an earning nature, conducted in an organized and continuous manner, carried out in one's own name, and resulting in revenues not classified under other specific statutory sources.[1]

An automated trading bot inherently fulfills several of these traditional criteria:

- **Earning Nature:** The exclusive programmatic purpose of DEX arbitrage and DeFi liquidation is the systematic extraction of profit.
- **Organized Manner:** Architecting algorithms, establishing multi-jurisdictional VPS hosting, configuring premium RPC nodes, and integrating flash loan smart contracts necessitate a high degree of technical, financial, and operational organization.[1]
- **Continuous Manner:** A bot operates perpetually, monitoring mempools and liquidity pools 24 hours a day, 7 days a week, executing transactions without human intervention or fatigue.[4]

Historically, within the context of traditional financial instruments, foreign exchange (Forex), or real estate, regular and highly organized trading of this magnitude frequently compelled tax authorities to unilaterally reclassify private investing into business activity. However, the Polish legislature introduced a distinct, isolated ring-fencing mechanism specifically designed for virtual currencies.

2.2 The Statutory Ring-Fence for Virtual Currencies (Article 17)

The taxation of virtual currencies in Poland underwent a fundamental restructuring with the regulations effective from 2019. Under Article 17 ust. 1f of the PIT Act, revenues derived from the exchange of virtual currency for legal tender, goods, services, or property rights other than virtual currency are explicitly and exclusively classified as revenues from capital gains (Article

10 ust. 1 pkt 7 of the PIT Act).[3]

Crucially, this classification is reinforced by Article 17 ust. 1g, which dictates a statutory override: income from the disposal of virtual currencies remains classified as capital gains *even if* it is achieved within the scope of a formally registered and operating business activity.[3] This means that if a business entity trades cryptocurrency, those specific profits are stripped out of the standard business operational income and taxed separately under capital gains rules. There is, however, one absolute exception to this rule: activities defined under Article 2 ust. 1 pkt 12 of the Anti-Money Laundering and Countering the Financing of Terrorism (AML/CFT) Act.[3]

2.3 The AML Override: Deconstructing Article 2 ust. 1 pkt 12

To determine if the high-frequency bot operation falls into the business category, it must be evaluated against the AML Act exception. If the bot's operation fits the AML definition of a crypto business, it loses the PIT-38 capital gains shield and becomes standard business income.[3]

The AML Act explicitly defines a regulated virtual currency business as providing services in:

1. Exchanging virtual currencies and means of payment (fiat currency).[7]
2. Exchanging virtual currencies for other virtual currencies.[7]
3. Intermediation in the aforementioned exchanges.[7]
4. Operating accounts (wallets) for authorized users to utilize virtual currency units.[7]

When a software developer runs an arbitrage or liquidation bot utilizing entirely *proprietary funds* and interacting directly with decentralized, non-custodial protocols, they are acting as a principal market participant.[1] The bot does not custody third-party assets, it does not provide an exchange interface for retail clients, nor does it intermediate trades between two outside entities.[3]

Trading strictly on one's own account—regardless of the algorithmic volume, technological sophistication, or cross-chain frequency—falls categorically outside the AML Act's definition of providing a virtual currency service.[1] Therefore, because the activity does not trigger the AML exception, Article 17 ust. 1g holds firm: the revenues remain firmly entrenched within the capital gains source.[3]

2.4 Jurisprudential Anchor: Analysis of Recent KIS Interpretations

The theoretical framework outlined above has been forcefully validated by recent individual tax rulings (*Interpretacje Indywidualne*) issued by the Director of the National Revenue Information (KIS), which explicitly protect algorithmic crypto trading from business reclassification.

In a landmark ruling, 0115-KDIT1.4011.582.2025.1.MR (issued in late 2025), KIS addressed a scenario practically identical to the one under review. An IT entrepreneur operating a software development firm intended to deploy automated tools ("bots" and algorithmic grid trading) operating continuously 24 hours a day to trade cryptocurrencies using private funds.[4] The Director of KIS confirmed the taxpayer's position in full: because the funds were private, no

external infrastructure was utilized for clients, and no services were rendered to third parties, the activity does not constitute business income.[3] It remains strictly within the capital gains source, subject to the flat 19% PIT-38 tax, entirely independent of the individual's IT business.[3]

Further solidifying this stance, in ruling 0112-KDIL2-2.4011.234.2025.3.AA, KIS established a vital precedent regarding volume. The authority ruled that "the intensity and volume of transactions do not prejudge the change of qualification of the obtained revenues".[3] A taxpayer executing thousands of algorithmic trades daily via a private portfolio remains legally categorized as a private investor. The fundamental absence of an organized enterprise offering exchange services to external clients prevents the tax authority from forcing the activity into the progressive or linear business tax brackets (PIT-36/PIT-36L).[3]

2.5 Reclassification Risks and the JDG Ryczałt 12% Interface

The taxpayer currently operates a JDG utilizing the highly favorable 12% *ryczałt od przychodów ewidencjonowanych* (lump-sum tax on recorded revenues) specifically for software development under the Polish Classification of Activities (PKD) code 62.01.B.[12]

Because the bot trading is definitively established as private capital gains (PIT-38), it has absolutely no legal or fiscal impact on the JDG's standing.[14] The 12% flat rate for IT services remains securely intact.[12] The revenues generated from software development clients are recorded in the JDG ledger and taxed at 12% via the PIT-28 form. Concurrently, the profits accumulated from the crypto bots are tracked separately, aggregated annually, and taxed at 19% via the PIT-38 form.[14]

However, a critical compliance requirement to maintain this optimal dual-structure is the strict enforcement of a "Chinese Wall" principle. No business assets, accounts, or resources should be demonstrably used for the private algorithmic bots. The bot's base capital must be funded exclusively from personal bank accounts, not the JDG operational account.[4] Cloud infrastructure (VPS, AWS) used to host the bot should be billed to the individual as a consumer, not expensed as a business cost in the JDG ledger. While under the *ryczałt* scheme, costs are not deducted anyway, mingling server invoices into the company's operational records could invite administrative scrutiny and blur the lines between private capital management and business operations.[4]

Furthermore, the developer must not attempt to classify the time spent writing the bot's smart contracts or Python/Rust backend code as a "service" provided to their own JDG. The software itself is a private tool and cannot be capitalized or amortized within the business entity.

2.5.1 The Disaster Scenario: Forced Reclassification

If, hypothetically, the developer were to open the bot's strategies to external capital (e.g., managing friends' funds or creating a smart contract vault where third parties deposit tokens for a performance fee), the activity would instantly cross the threshold into AML Article 2 ust. 1 pkt 12.[7]

In this scenario of forced business reclassification, the consequences are severe:

- **Tax Form:** The income moves from the PIT-38 capital gains form to standard business forms (PIT-36 or PIT-36L).[14]
- **Tax Rate:** The taxpayer would likely be forced to pay progressive tax (12% up to 120,000 PLN, 32% above) or opt for the 19% linear tax on this income.[14]
- **ZUS Obligations:** The trading income would become part of the basis for calculating mandatory health insurance contributions (składka zdrowotna), effectively adding a 4.9% or 9% hidden tax on the bot's profits.[18]
- **AML Registration:** The developer would be legally mandated to enter the Register of Virtual Currency Business Activities, subject to strict audits, KYC/AML procedural requirements, and potential administrative fines up to 100,000 PLN for non-compliance.[8]

By strictly limiting the bot to proprietary funds, the developer entirely sidesteps this administrative and financial disaster.

3. The Mechanics and Taxation of High-Frequency DEX Arbitrage

A central, highly active feature of the deployed bots is automated DEX-to-DEX arbitrage. In practice, the bot continuously scans decentralized exchange liquidity pools (e.g., Uniswap on Ethereum vs. SushiSwap on Arbitrum) for pricing inefficiencies. Upon detecting an imbalance, the bot executes an atomic transaction—buying an asset low on one DEX and instantly selling it for a higher price on another within the very same transaction block. These transactions occur strictly between different virtual currencies (crypto-to-crypto) and are executed at extraordinarily high frequencies, potentially logging hundreds of thousands of transactions annually.

3.1 The Absolute Principle of Crypto-to-Crypto Tax Neutrality

The taxation of such granular, high-frequency activity would be computationally and administratively paralyzing. Recognizing the unique nature of digital asset ledgers, the Polish legislature established a principle of absolute tax neutrality for intra-crypto exchanges. Under Article 17 ust. 1f of the Polish PIT Act, a taxable event is strictly and exhaustively defined.[3] It requires the disposal of a virtual currency in direct exchange for legal tender (fiat currency), a traditional good, a service, or a property right other than another virtual currency.[3]

Consequently, the exchange of one virtual currency for another virtual currency is statutorily tax-neutral.[14] This principle applies uniformly regardless of the specific tokens involved. Whether the bot is engaging in volatile asset arbitrage (swapping ETH for UNI) or routing transactions through stable liquidity pools, the transaction intrinsically fails to generate taxable revenue in the eyes of the National Revenue Administration (KAS).[20]

3.2 The "Fiat Exit" Trigger and Stablecoin Safe Harbors

Because of this profound tax neutrality, an algorithmic arbitrage bot could theoretically execute millions of highly profitable crypto-to-crypto trades over the course of a fiscal year. A

developer could grow an initial portfolio of 10 ETH into 1,000 ETH entirely on-chain, and the taxpayer would incur absolutely **zero income tax liability** for that specific fiscal year, provided no portion of that portfolio was liquidated into traditional fiat currency.[14]

The tax obligation crystallizes exclusively at the point of the "fiat exit".[20] If the developer manually withdraws accumulated USDC from the bot's decentralized multi-signature wallet, transfers it to a centralized exchange operating with fiat gateways (e.g., Kraken or Binance), and converts the stablecoins to EUR or PLN, only that specific conversion constitutes a taxable disposal.[5]

In this context, stablecoins such as USDC, USDT, or DAI act as an essential tax-deferral mechanism. Under current Polish legal frameworks, stablecoins are classified legally as virtual currencies, as they rely fundamentally on cryptographic security and distributed ledger technology to function. They are not considered electronic money (e-money) or legal fiat currency equivalents by the PIT Act.[20] Therefore, a bot strategy designed to automatically park extracted profits in USDC during high volatility periods successfully defers taxation while mitigating market risk. The Polish tax authorities do not currently apply a "substance over form" doctrine to reclassify fiat-pegged stablecoins as fiat currency, meaning the crypto-to-crypto exemption remains highly robust.[20]

3.3 Navigating Future MiCA Implications

While the current framework is stable, significant caution is required regarding the impending, comprehensive implementation of the Markets in Crypto-Assets (MiCA) regulation across the European Union. MiCA introduces nuanced, granular classifications of digital assets, primarily distinguishing between "E-Money Tokens" (EMTs), which are pegged to a single fiat currency, and "Asset-Referenced Tokens" (ARTs), which are pegged to a basket of assets.[21]

While Polish tax law currently groups all decentralized and centralized stablecoins under the monolithic umbrella of "virtual currencies," future harmonization of the PIT Act with MiCA definitions could potentially alter the tax-neutral status of certain tokens. If domestic tax definitions are amended to treat highly regulated EMTs as exact legal equivalents of fiat currency, the swap of ETH to USDC could suddenly become a taxable disposal. Under the current 2025/2026 framework, however, the legislation has not yet bridged this gap, and swapping volatile crypto to stablecoins remains a non-taxable event.

3.4 Volume Thresholds and the Irrelevance of Transaction Frequency

A common point of anxiety for algorithmic traders is the fear that sheer transaction volume will trigger algorithmic audits by the tax office. As analyzed in the classification section, KIS has repeatedly affirmed that frequency does not dictate the nature of the income.[3] The execution of 365,000 trades annually by a Python script interacting with Uniswap routers is treated identically to a retail investor making three manual trades a year, provided the trades remain crypto-to-crypto. The volume is statistically aggregated and, if no fiat is involved, entirely legally invisible for the calculation of current-year tax liability.

4. DeFi Liquidations: Programmatic Rewards and Cost Basis Mechanics

The second primary function of the deployed bot ecosystem focuses on executing liquidations within decentralized lending protocols. Protocols such as Aave, Compound, and Morpho allow users to deposit collateral and borrow against it. If the value of the collateral falls below a mathematically defined maintenance threshold, the position becomes eligible for liquidation to protect the protocol from bad debt. The automated bot continuously monitors the blockchain state for these under-collateralized loans. Upon detection, it triggers a liquidation function, repays a portion of the user's outstanding debt (often utilizing a flash loan to source the capital), and in return, receives the user's collateral along with a liquidation penalty or bonus (typically ranging from 5% to 10% of the liquidated value).

4.1 The Ontological Nature of Liquidation Bonuses

The legal and fiscal nature of receiving a liquidation bonus in the DeFi space lacks a direct, codified precedent in traditional Polish tax law. However, its mechanics heavily parallel the established tax treatment of airdrops, hard forks, and Proof-of-Stake (PoS) staking rewards.[2]

When the bot successfully processes a liquidation, it experiences a net influx of virtual currency (e.g., 0.1 ETH representing the bonus) into its wallet. From a legal perspective, two potential classifications exist:

1. **Service Provision Model:** The bot is conceptually "providing a service" to the decentralized protocol by ensuring its solvency and eliminating bad debt. In this model, the bonus represents remuneration for services rendered.
2. **Unilateral Programmatic Acquisition:** The bot is simply interacting with an autonomous, open-source smart contract without any formal bilateral agreement. It receives a programmatic asset transfer determined by algorithmic rules, highly analogous to a miner receiving a block reward.

Polish tax jurisprudence, which has established extensive precedent around cryptocurrency mining and airdrops, explicitly rejects the service provision model for automated, permissionless protocol interactions.[2] A fundamental requirement for a service contract is the existence of two identifiable legal entities. Because the protocol is merely a series of autonomous smart contracts deployed on a blockchain, there is no legal counterpart with which the bot operator can form a service contract.[2] Therefore, receiving the liquidation bonus is definitively treated as a unilateral, non-contractual acquisition of a virtual currency.[2]

4.2 Establishing the Zero Cost Basis Paradigm

Under the established practice of the National Revenue Information (KIS), the mere receipt of virtual currency for free, or as a programmatic reward resulting from network participation, does **not** constitute a taxable event at the precise moment of receipt.[2] The taxable event is

structurally deferred until the ultimate disposal of that specific virtual currency for fiat.[2]

Crucially, because the liquidation bonus (the net profit fraction of the seized collateral) was acquired without an associated, documented fiat expenditure by the developer, its **tax cost basis is mathematically zero**. When the developer eventually converts that 0.1 ETH into fiat currency on an exchange, the entire fiat value received constitutes taxable income, with absolutely no acquisition cost available to offset or reduce it. The profit is pure, and so is the taxable base upon disposal.

5. The Deductibility Crisis: Gas Fees, Flash Loans, and Infrastructure

While the capital gains classification (PIT-38) effectively shields the taxpayer from progressive tax rates and mandatory social security (ZUS) obligations, it imposes an exceptionally rigid, almost draconian framework regarding the deductibility of operational costs. The friction between the economic realities of high-frequency DeFi trading and the strict textual interpretation of the Polish PIT Act creates a significant operational crisis.

Article 22 ust. 14 of the PIT Act defines the costs of obtaining revenues from the disposal of virtual currencies strictly as "documented expenses directly incurred for the acquisition of virtual currency and costs related to its disposal".[6]

5.1 The Crypto-to-Crypto Exclusion (Article 23 ust. 1 pkt 38d)

The most detrimental statutory provision for automated bot operators is Article 23 ust. 1 pkt 38d of the PIT Act. This specific article explicitly and unequivocally states that expenses incurred on the exchange of one virtual currency for another virtual currency cannot be classified as tax-deductible costs.[6]

The Gas Fee Dilemma

When a bot performs an arbitrage trade between Uniswap and SushiSwap, it must pay a network gas fee (typically in ETH) to the validators to process the transaction. Because this entire arbitrage trade is legally classified as a crypto-to-crypto exchange, the gas fee is inextricably linked to an exempt, non-taxable transaction. Consequently, **gas fees paid on crypto-to-crypto arbitrage trades are strictly non-deductible**.[6]

To quantify the severity of this rule: If a high-frequency bot executes 1,000 trades a day, paying an average of $1 in gas per trade, it incurs $365,000 in real economic operational costs annually. Under Article 23 ust. 1 pkt 38d, this entire $365,000 is legally invisible as an expense and cannot be used to reduce the tax base when the bot's remaining net profits are eventually converted to fiat.[6]

Flash Loan Premiums as Sunk Costs

Similarly, to execute massive arbitrage without holding millions in capital, bots frequently employ flash loans—borrowing vast sums of crypto, utilizing it to balance a pool, and repaying

the principal plus a fee (e.g., 0.09% on Aave) within a single block. The fee paid to execute a flash loan is paid in crypto as an inherent part of a crypto-to-crypto operational chain.

Furthermore, the Polish Ministry of Finance has explicitly ruled that costs related to financing the purchase of cryptocurrencies, such as interest on standard loans or credits, are categorically non-deductible.[6] Therefore, flash loan premiums represent "dead capital" from a tax perspective. They drastically reduce the bot's real economic profit margin, but they provide absolutely no tax relief against the taxpayer's final fiat-realized taxable base.

The Exception: Gas Fees on Fiat Disposals

The only gas fees that *are* legally deductible under this stringent framework are those directly incurred during the ultimate disposal of crypto for fiat.[6] If the developer initiates a transaction to transfer USDC from the bot's hardware wallet to a centralized exchange to sell for EUR, the ETH gas fee paid to execute that specific transfer is theoretically classified as a "cost directly related to disposal" and can be deducted.

5.2 Failed Transactions and MEV Losses

In the highly adversarial environment of high-frequency DeFi trading and Maximal Extractable Value (MEV), transactions frequently revert. A transaction may fail because another bot front-ran the trade, or because slippage tolerances were exceeded. When a transaction reverts, the smart contract state rolls back, but the gas fee is still consumed and kept by the network validators.

Because the transaction failed, no virtual currency was actually acquired or disposed of. Therefore, the gas fee cannot be legally tied to an "acquisition" or "disposal" event, which is the foundational requirement of Article 22 ust. 14.[6] The gas fee for a failed transaction is essentially an absolute sunk cost and is entirely non-deductible under Polish law.[6]

5.3 Indirect Costs: Servers, Software, and Infrastructure

To run a competitive bot, a developer requires premium infrastructure: virtual private servers (VPS) hosted geographically close to validator nodes, premium RPC endpoints for rapid block propagation, and specialized development software.

Under the PIT-38 framework, only *direct* costs of acquiring crypto are deductible.[6] The Ministry of Finance and KIS have established a rigid, unyielding precedent regarding cryptocurrency mining, which serves as the closest operational parallel. Rulings consistently state that the costs of purchasing mining rigs, electricity consumption, and internet access are indirect operational costs and cannot be deducted against the sale of the mined cryptocurrency.[6]

By direct legal analogy, the costs of server hosting (e.g., Hetzner, AWS monthly bills), RPC endpoint subscriptions, and expenses related to bot software development are considered indirect tools utilized to facilitate the general acquisition of crypto.[17] They are **not** deductible as direct costs of obtaining revenue in PIT-38.[6]

Furthermore, because the bot operation is strictly classified as private investing and

partitioned away from the JDG, these server costs cannot be pushed into the JDG's accounting ledger. Even if they were erroneously included, the 12% *ryczałt* scheme structurally does not allow for any cost deductions whatsoever, rendering the point moot from a tax reduction perspective.

Expense Category	Deductible under PIT-38?	Statutory / Interpretative Basis
Initial Fiat Purchase of Crypto	**Yes**	Art. 22 ust. 14 (Direct acquisition cost) [6]
Fiat Exchange Trading Commissions	**Yes**	Art. 22 ust. 14 (Direct acquisition/disposal cost) [17]
Gas Fees on Crypto-to-Crypto Arbitrage	**No**	Art. 23 ust. 1 pkt 38d (Crypto-crypto exclusion) [14]
Flash Loan Fees / Premiums	**No**	Art. 23 ust. 1 pkt 38d & Financing exclusion [6]
Gas Fees on Reverted/Failed Transactions	**No**	Fails Art. 22 ust. 14 (No acquisition/disposal occurred) [6]
Server Hosting (VPS) / RPC Endpoints	**No**	Classified as indirect costs (similar to mining gear) [6]

6. Multi-Jurisdictional Tax Exposure and Permanent Establishment (PE)

Automated bots require incredibly low latency to succeed in competitive arbitrage and liquidation environments. Consequently, Polish developers frequently host their algorithms and execution engines on dedicated servers located in jurisdictions with dense, highly optimized blockchain infrastructure, such as Germany (e.g., Hetzner data centers in Falkenstein) or Japan (e.g., AWS Tokyo region). This deployment strategy raises complex questions regarding international tax exposure and the potential creation of a Permanent Establishment (PE).

6.1 Tax Residency and Worldwide Income

As a registered Polish tax resident, the developer is legally subject to unlimited tax liability

(*nieograniczony obowiązek podatkowy*) under Article 3 ust. 1 of the PIT Act.[28] This sweeping provision means that the taxpayer's worldwide income, regardless of the geographic location where it is generated, stored, or processed, is inherently subject to taxation in Poland.[1]

6.2 The Permanent Establishment (PE) Risk Architecture

The core international tax risk in deploying technical infrastructure abroad is whether the host country (e.g., Germany or Japan) considers that specific infrastructure to constitute a Permanent Establishment. If a PE exists, the host country gains the sovereign right to tax the profits specifically attributable to that establishment under the rules of the respective Double Taxation Treaties (DTTs).[29]

Under Article 5 of the OECD Model Tax Convention (which forms the textual and conceptual basis for Poland's DTTs with both Germany and Japan), a PE is broadly defined as a "fixed place of business through which the business of an enterprise is wholly or partly carried on".[32] Historically, the status of computer servers has been a point of intense contention in international tax law. The official OECD commentary explicitly notes that a server *can* technically constitute a PE if it is entirely at the disposal of the enterprise and fixed in a specific geographic location.[32]

However, two critical legal defenses robustly neutralize this risk for the private bot operator:

1. The "Enterprise" Requirement: A Permanent Establishment, by definition, applies specifically to the *business profits* (governed by Article 7 of the DTT) of a recognized *enterprise*. As exhaustively established in Section 2 of this report, the Polish tax authority securely classifies this specific proprietary bot trading as private capital gains (governed by Article 13 of the DTT equivalent), explicitly denying it the status of a business enterprise.[3] A private individual managing their personal wealth via a remote server does not generate "business profits" and does not constitute an "enterprise" capable of forming a PE under traditional treaty definitions.

2. The Preparatory or Auxiliary Exception: Even if German tax authorities (e.g., the *Bundeszentralamt für Steuern*) attempted an aggressive reclassification of the bot as an enterprise, renting virtual space on a highly distributed cloud server (AWS or Hetzner VPS) where the taxpayer has absolutely no physical access to the underlying hardware generally does not create a "fixed place of business".[31] Furthermore, automated equipment running continuously without on-site personnel is frequently protected by treaty clauses if the activity is deemed to be of a "preparatory or auxiliary character".[33] While the bot executes the core trades, the total lack of human agents, physical operational presence, and the purely proprietary nature of the capital gains make it highly improbable that foreign tax authorities would successfully claim a PE for a retail individual's rented VPS.[31]

6.3 Location of the Smart Contract

DeFi protocols (such as Uniswap or Aave) reside on decentralized blockchains (Ethereum, Arbitrum). A smart contract is merely compiled bytecode distributed across thousands of

nodes globally; it has no single physical geographic location or distinct tax residency. For tax purposes, the jurisdiction is determined entirely by the tax residency of the individual exercising cryptographic control over the private keys that sign the transactions.[28] Thus, Polish residency anchors the entire tax obligation firmly in Poland, rendering the abstract "location" of the blockchain protocol entirely irrelevant.[28]

7. Practical Reporting Methodology, Documentation, and the Annual Cost Pool

The statistical aggregation and accurate tax reporting of high-frequency DeFi trading present severe logistical and evidentiary challenges. A bot executing a conservative 1,000 trades daily generates 365,000 discrete on-chain events annually, all of which must be aggregated, analyzed, filtered, and ultimately consolidated into a single Polish PIT-38 tax form.

7.1 The Annual Cost Pool Method vs. FIFO

Polish cryptocurrency tax law employs a highly simplified, aggregate "Cost Pool" (*pula kosztów*) methodology, firmly rejecting the complex FIFO (First-In, First-Out), LIFO, or Specific Identification tracking methods required by jurisdictions like the United States.[14]

Under this method, the taxpayer aggregates data into two distinct, monolithic buckets for the fiscal year:

1. **Total Acquisition Costs:** The aggregate fiat value of all funds ever spent to acquire cryptocurrency during the year, plus any unused carried-over costs from previous tax years.[6]
2. **Total Disposal Revenues:** The aggregate fiat value of all cryptocurrency sold for fiat currency, goods, or services during the year.[6]

The tax calculation is entirely straightforward:

- If Revenue exceeds Costs, the difference constitutes the Taxable Income, which is taxed at the flat 19% rate.[6]
- If Costs exceed Revenue (e.g., the developer spent 25,000 EUR buying ETH but only cashed out 1,000 EUR), the tax liability is strictly zero. The excess unused costs are formally reported in PIT-38 Box 36 ("Koszty uzyskania przychodów poniesione w latach ubiegłych") to be carried forward indefinitely to offset capital gains in subsequent tax years.[6]

7.2 Evidentiary Standards in a Decentralized Landscape

In traditional finance, licensed domestic brokers issue a standardized PIT-8C form summarizing all gains and losses, which the tax authority automatically receives.[34] In the decentralized DeFi ecosystem, there are no brokers. The burden of proof to substantiate costs and revenues falls entirely and unforgivingly on the taxpayer.[35]

The impending EU DAC8 directive will legally force centralized exchanges operating within Europe (such as Binance, Kraken, or Coinbase) to report user deposit and withdrawal data directly to the Polish National Revenue Administration (KAS) by 2026.[35] This means the tax authority will know exactly how much fiat the developer injects and extracts. However, DAC8 is technologically incapable of tracking decentralized, permissionless on-chain arbitrage.[35]

To accurately document costs and prove the tax-neutrality of the internal crypto-to-crypto flows, the taxpayer must maintain rigorous, immutable records. According to standard KIS interpretations and Supreme Administrative Court (NSA) jurisprudence (e.g., ruling II FSK 3796/18), acceptable documentation includes:

- Bank transfer confirmations to centralized exchanges proving the initial fiat injection.[14]
- Electronic statements or CSV history exports from centralized exchanges.[14]
- For on-chain activity: Cryptographic signatures, comprehensive block explorer exports (e.g., Etherscan CSVs), and proof of wallet address ownership.[14]

Given the extreme volume (365,000+ trades), manual calculation is impossible. The developer is practically mandated to utilize specialized enterprise crypto tax software (e.g., Koinly, Cointracker). The software must be configured specifically for Polish law to parse the blockchain data, isolate and ignore the crypto-to-crypto trades (to exclude them from being erroneously calculated as revenue), and accurately price the fiat-to-crypto entry and exit points using the official daily National Bank of Poland (NBP) average exchange rate from the exact business day preceding the transaction.[14]

8. Applied Scenarios: Tax Liability Calculations

To fully contextualize the theoretical framework constructed above, we map the developer's specific algorithmic activities to the mechanical realities of PIT-38 reporting.

8.1 Scenario Alpha: High-Frequency DEX Arbitrage

Parameters:

1. The developer transfers 25,000 EUR from a private personal bank account to Kraken and purchases 10 ETH.
2. The 10 ETH is withdrawn and sent to a decentralized non-custodial wallet controlled exclusively by the automated bot.
3. Over a 12-month period, the bot executes 50,000 atomic arbitrage trades (swapping ETH for USDC and vice versa) across various DEXs using flash loans.
4. The bot burns 1.5 ETH in network gas fees and pays 0.5 ETH in flash loan premiums to lending pools over the year.
5. Net operational result: The bot's final balance stands at 12 ETH and 500 USDC.
6. The developer decides to take profit, transferring only the 500 USDC back to Kraken, converting it to 450 EUR, and leaves the 12 ETH active on-chain for future operations.

Tax Calculation & Reporting Mechanics:

- **Acquisition Cost Creation:** The initial 25,000 EUR spent on Kraken is converted to PLN using the NBP exchange rate from the day preceding the purchase.[14] This PLN value constitutes the total *Koszty uzyskania przychodów* (Deductible Costs) for the fiscal year.
- **Crypto-to-Crypto Invisibility:** The 50,000 on-chain trades generate **zero** reportable revenue.[17] They are completely ignored on the PIT-38 form.
- **The Cost Trap Execution:** The 1.5 ETH lost to gas and 0.5 ETH paid in flash loan fees are strictly non-deductible.[6] They represent a real economic cost to the developer, reducing their holdings, but because they facilitated crypto-to-crypto trades, they cannot be added to the official cost pool.
- **Revenue Realization:** The conversion of 500 USDC to 450 EUR is the sole taxable event. The 450 EUR is converted to PLN via the NBP rate from the preceding day. This figure is entered as *Przychód* (Revenue).[14]
- **Net Tax Result:** The calculation is simply Revenue (450 EUR in PLN) minus Costs (25,000 EUR in PLN). Because the accumulated Costs vastly exceed the nominal Revenue, the Taxable Income is officially 0 PLN.[6]
- **PIT-38 Filing Action:** The developer is legally obligated to file PIT-38, reporting both the revenue and the costs. The excess cost (roughly equivalent to 24,550 EUR) is entered into Box 36 ("Koszty uzyskania przychodów poniesione w latach ubiegłych i niepotrącone w poprzednim roku podatkowym") to be carried forward to offset future gains indefinitely.[6]
- **JDG / PIT-28 Action:** Absolutely none. This remains entirely detached from the software business.[14]

8.2 Scenario Beta: Flash-Loan Enabled DeFi Liquidation

Parameters:

1. The bot monitors the Aave protocol and executes a successful liquidation, receiving a penalty bonus of 0.1 ETH directly into its wallet. No initial fiat capital was deployed; the transaction was funded entirely by an atomic flash loan.
2. To lock in the profit and mitigate volatility, the bot immediately swaps the 0.1 ETH for 300 USDC.
3. Six months later, the 300 USDC is transferred to Kraken and converted to 280 EUR.

Tax Calculation & Reporting Mechanics:

- **Receipt of the Liquidation Bonus:** The programmatic receipt of 0.1 ETH generates no immediate tax obligation. It is legally treated as an acquisition with a cost basis of mathematically zero.[2]
- **Swap to Stablecoin:** The swap of 0.1 ETH to 300 USDC is a crypto-to-crypto transaction and remains entirely tax-neutral.[20]
- **Conversion to Fiat:** The final sale of 300 USDC for 280 EUR on the centralized exchange triggers the tax obligation.[5]
- **Net Tax Result:** Revenue = 280 EUR (converted to PLN). Deductible Costs = 0 PLN (since the 0.1 ETH was a programmatic bonus and no fiat was originally spent to acquire it).

- **Tax Liability:** The developer pays the flat 19% capital gains tax on the entire PLN value of the 280 EUR, entered in the PIT-38 form for the year the conversion occurred.[14]

9. Concluding Synthesis and Strategic Posture

The operation of highly sophisticated, automated liquidation and arbitrage bots under Polish jurisdiction offers a remarkably advantageous legal framework, albeit one fraught with severe mechanical inefficiencies regarding the deduction of operational overhead.

The Shield of Capital Gains: The most critical strategic victory for the developer is the preservation of the PIT-38 (19%) classification. By ensuring that all automated bot operations are conducted utilizing exclusively personal, proprietary funds without providing exchange or wallet services to any third parties, the developer actively avoids triggering the AML Act's definition of a virtual currency business (Article 2 ust. 1 pkt 12). This structural decision permanently immunizes the trading profits from being dragged into the JDG. It protects the highly favorable 12% *ryczałt* status for the core software development business and successfully averts the imposition of progressive tax rates or heavy mandatory social security (ZUS) contributions on the trading profits.

The Friction of the Cost Pool: The primary vulnerability of this operational setup is the inescapable "Cost Trap" imposed by Article 23 ust. 1 pkt 38d. Because high-frequency DEX arbitrage is fundamentally reliant on massive transaction volumes and complex smart contract interactions, the accumulated network gas fees and flash loan premiums represent massive, continuous capital outflows. The statutory inability to deduct these crypto-to-crypto friction costs against final fiat-realized profits means that the developer's *effective* tax rate on real, bottom-line economic profit will always be substantially higher than the nominal 19% statutory rate.

International Security: Hosting technical infrastructure via Hetzner in Germany or AWS in Japan presents negligible Permanent Establishment risks under current treaty interpretations. The non-enterprise nature of private capital gains trading, combined seamlessly with the lack of human agents or fixed operational bases in the host countries, ensures that worldwide income remains exclusively taxable in Poland under unlimited tax liability doctrines.

Compliance Imperatives: The developer must maintain an immaculate, audited separation between the JDG and private trading operations. Mixing server costs, utilizing JDG corporate bank accounts to fund the bot, or attempting to claim bot development time as a business expense risks blurring the critical legal lines, potentially inviting the National Revenue Administration to reclassify the trading as an unregistered, highly taxed arm of the IT business. Furthermore, with DAC8 implementation forcing European centralized exchanges to automatically report fiat off-ramps by 2026, the developer must deploy robust, enterprise-grade crypto tax aggregation software. This is essential to trace the exact cryptographic provenance of every stablecoin back through the tens of thousands of tax-neutral on-chain arbitrage loops to fully substantiate the final PIT-38 filing.

Ultimately, Polish tax law rewards the holder and the strategic extractor over the active trader.

The absolute tax neutrality of crypto-to-crypto transactions allows algorithmic bots to compound capital endlessly in the decentralized environment without structural tax drag, provided the developer carefully orchestrates the timing, scale, and exact documentation of the inevitable fiat exits.
